## GPS TO TRACKER DIRECT CONNECTION

### Electrical connection

Apart from the connections that are for the tracker's operation, the GPS is connected in a way to show the image. The tracker has a network board that the GPS network is connected to.

The 12 volt power supply for the GPS is done as shown in the image.

### Operation

The control unit will take the data in the following way:

If it is switched off and started again, after exactly 3 minutes, it will take the data for the latitude and longitude of the place and the year, day, hour, minute and seconds. This data will be saved in the memory. The tracker is then restarted. That is to say, it will start to move to the east and the entire operation will restart.

Another way of doing it is: turn the breaker off, start it up again, and before two seconds pass press the blue button for 8 seconds. This is when it will take the GPS data and restart.

At night, when the sun is 10° under the horizon, the tracker control will automatically take the date and time of the GPS.
